Hypo- and hypercapnia predict mortality in oxygen-dependent chronic obstructive pulmonary disease: a population-based prospective study

Abstract

Background: The prognostic role of the arterial blood gas tension of carbon dioxide (PaCO2) in severe Chronic Obstructive Pulmonary Disease (COPD) remains unknown. The aim of this study was to estimate the association between PaCO2 and mortality in oxygen-dependent COPD.

Methods: National prospective study of patients starting long-term oxygen therapy (LTOT) for COPD in Sweden between October 1, 2005 and June 30, 2009, with all-cause mortality as endpoint. The association between PaCO2 while breathing air, PaCO2 (air), and mortality was estimated using Cox regression adjusted for age, sex, arterial blood gas tension of oxygen (PaO2), World Health Organization performance status, body mass index, comorbidity, and medications.

Results: Of 2,249 patients included, 1,129 (50%) died during a median 1.1 years (IQR 0.6-2.0 years) of observation. No patient was lost to follow-up. PaCO2 (air) independently predicted adjusted mortality (p < 0.001). The association with mortality was U-shaped, with the lowest mortality at approximately PaCO2 (air) 6.5 kPa and increased mortality at PaCO2 (air) below 5.0 kPa and above 7.0 kPa.

Conclusion: In oxygen-dependent COPD, PaCO2 (air) is an independent prognostic factor with a U-shaped association with mortality.

Keywords: COPD, LTOT, Mortality, PaCO2, Hypercapnia, Carbon dioxide, Respiratory failure, Survival

Introduction

Advanced chronic obstructive pulmonary disease (COPD) is associated with high morbidity and mortality [1]. Although long-term oxygen therapy (LTOT) decreases mortality in patients with advanced COPD and chronic hypoxemia [2,3], the prognosis is poor with a mortality rate of 51% at 2 years [4]. Predictors of mortality in oxygen-dependent COPD include sex, age, body mass index (BMI), comorbidities, forced expiratory volume in one second (FEV1), and arterial blood gas tension of oxygen (PaO2) [5-14].

The prognostic role of PaCO2 in oxygen-dependent COPD remains unknown. PaCO2 while breathing air, PaCO2 (air), has been associated with both increased mortality [5], decreased mortality [15], and no association with mortality [4,16].

Defining the predictive role of PaCO2 (air) on mortality is important for several reasons. Despite the data being inconsistent, clinicians often regard hypercapnia (PaCO2 > 6.5 kPa) as an indicator of more severe respiratory disease, worse prognosis, and higher risk of complications from oxygen therapy including respiratory depression. High-flow oxygen given pre-hospital to patients with likely COPD exacerbation was recently associated with increased risk of acute hypercapnia and mortality [17]. Guidelines recommend titration of oxygen dose in hospital to avoid possible adverse effects when LTOT is initiated in a patient with hypercapnia [18]. Hypercapnia might indicate the presence of a concurrent hypoventilation syndrome in COPD, which is associated with shorter survival [19]. In addition, knowledge on

predictors of mortality is needed as a prognostic model for patients with oxygen-dependent COPD is lacking.

The aim of this nationwide prospective study was therefore to estimate the association between PaCO₂ (air) and mortality in oxygen-dependent COPD.

Materials and methods

We prospectively included patients from the National Register for Long Term Oxygen Therapy (Swedevox) with physician-diagnosed COPD who started LTOT between October 1, 2005 and June 30, 2009. Swedevox is a health quality register run by the health professionals and with financial support from the government. Swedevox has a population-based coverage of approximately 85% of patients starting LTOT in Sweden since 1987 [20]. Details of the register were described in a recently published study using the same database [21]. For patients who had started LTOT more than once (n = 62), only the most recent treatment episode was included in the analysis. Exclusion criterion was a diagnosis of lung cancer before starting LTOT (baseline).

Data on comorbidity and time spent in hospital during the four-year period before baseline were obtained from the National Patient Register for in- and outpatient care [22]. Diagnoses were coded according to the ninth (before 1997) [23] and tenth revisions of the International Classification of Disease (ICD) [24]. Possible comorbid hypoventilation was defined as hypoxia with a normal alveolar-arterial oxygen tension difference, (P[Aₐ-a]O₂), of < 3 kPa, or a prior diagnosis (ICD-9; ICD-10) which may cause hypoventilation [25]: scoliosis (737.4; M41), spinal muscular atrophy (335.1; G12), muscular dystrophy (335.2; G71), myasthenia gravis (358; G70), post-polio syndrome (138; G14), sequelae of poliomyelitis (B91.9), sequelae of respiratory tuberculosis (137; B90.9), obstructive sleep apnea (327.2; G47.3), obesity hypoventilation syndrome (278.0; E66.2), or prolonged mechanical ventilation (DG008, AG063; 93.90, 96.70).

Data on all dispensed drug prescriptions in outpatient care after July 1, 2005 were obtained from the Swedish Prescribed Drug Register [26]. Patients were followed until withdrawal of LTOT, death, or December 31, 2009, whichever came first. The primary endpoint was all-cause mortality, obtained from the Swedish Causes of Death Register.

All patients participating in the study were informed according to directives from the authorities. The study was approved by all the relevant ethics committees in Sweden, the Swedish National Board of Health and Welfare, and the Swedish Data Inspection Board.

Statistical analysis

Baseline patient characteristics were summarized using mean with standard deviation (SD) and median with range or interquartile range (IQR) for continuous variables with normal and skewed distribution, respectively. Categorical variables were expressed as frequencies and percentages. The differences among the groups were tested with t-test for continuous variables and chi-square test for categorical variables.

Missing elements were imputed for PaO₂ (air) (n = 289), PaCO₂ (air) (n = 301), PaO₂ (oxygen) (n = 210), PaCO₂ (oxygen) (n = 213), FEV₁ (n = 849), and body mass index (BMI) (n = 701), as previously described [21]. The model estimates were robust to the imputations. P[A-a]O₂ was calculated using the alveolar gas equation: P[A-a]O₂ = PₐO₂ - (PaCO₂/R) - PaO₂. Change in PaCO₂ was defined as a difference between PaCO₂ (oxygen) and PaCO₂ (air) of 0.3 kPa or more.

Association between PaCO₂ (air) and mortality was estimated using Cox multiple regression, adjusting for baseline age, sex, PaO₂ (air), World Health Organization (WHO) performance status, BMI, number of cardiovascular diagnoses (cerebrovascular disease, heart failure, hypertension, ischemic heart disease, peripheral artery disease, pulmonary embolism, and other circulatory disease), treatment with oral glucocorticoids, benzodiazepines, and opioids. The model included a linear and a squared term for PaCO₂ (air) to evaluate nonlinear associations. Higher-order terms did not improve the model with regard to diagnostics. Mortality estimates were expressed as hazard ratios (HRs) with 95% confidence intervals (CIs). Statistical significance was defined as a two-sided p-value of < 0.05.

Statistical analyses were conducted using the software packages Stata, version 12 (StataCorp LP; College Station, TX), and SAS, version 9.2 (SAS Institute, Inc., Cary, NC).

Results

A total of 2,249 patients were included. No patient was lost to follow-up. The cohort generated 3,118 person-years at risk during a median 1.1 years (IQR: 0.6–2.0 years) of follow-up. During this time, 1,129 (50%) patients died. The main causes of death were respiratory disease (68%), cardiovascular disease (20%), and cancer (6%). LTOT was withdrawn for other reasons than death in 138 (6%) patients, mainly because of improved oxygenation.

Patient characteristics at baseline are shown in Table 1. Hypocapnia (PaCO₂ (air) > 6.5 kPa) was present in 39% of patients. After initiating LTOT, PaCO₂ increased in 45% of patients, decreased in 19%, and remained unchanged (difference less than 0.3 kPa) in 36%. Of patients with hypocapnia, 37% increased in PaCO₂ after starting LTOT, whereas 30% decreased to a PaCO₂ below 6.5 kPa.

Hypocapnic patients were prescribed a slightly lower median oxygen dose than normocapnic patients, 1 (IQR, 1–1.5) vs. 1.5 (IQR, 1–2) l/min (p < 0.001). In total, 29%

Effects on mortality
PaCO2 (air) independently predicted adjusted mortality (p < 0.001), as shown in Table 2. The association with mortality exhibited a U-shaped pattern, with lowest mortality at approximately PaCO2 (air) 6.5 kPa and increased mortality below 5.0 kPa and above 7.0 kPa (Figure 1). Compared to a PaCO2 (air) of 6.5 kPa, a PaCO2 (air) of ≤ 4.5 kPa increased mortality by 17% or more, and a PaCO2 (air) of ≥ 8.0 kPa increased mortality by at least 15%. Excluding patients with possible hypoventilation (n = 122) did not alter the estimates. Sensitivity analysis only including patients with FEV1/FVC < 0.7 did not alter the results.

of patients started LTOT in hospital. A slightly greater proportion of patients with hypercapnia (31%) than normocapnic patients (27%) started LTOT in hospital (p = 0.039).

Discussion
The novel finding in the present study is that PaCO2 (air) has an U-shaped association with mortality in oxygen-dependent COPD. PaCO2 (air) values lower than 5.0 kPa and higher than 7.0 kPa were associated with increased mortality.

Previous findings on the association between PaCO2 and mortality have been conflicting. Our results are consistent with studies reporting increased mortality associated with either hypocapnia [5,27] or hypercapnia [3,28,29]. In a large study of COPD patients on LTOT, Chailleux et al. found PaCO2 to be an independent negative predictor at 3 years follow-up [5]. However, Aida and colleagues found no association between
PaCO$_2$ (air) and mortality [16]. As none of the previous studies, to our knowledge, evaluated the shape of the association, the discrepancy between the findings of previous studies may partly owe to that they did not account for a nonlinear association.

Strengths of the present study include its national prospective design and that it included a large cohort of both men and women with oxygen-dependent COPD. No patient was lost to follow-up. The analysis was adjusted for relevant confounders, including comorbidity and exposure to benzodiazepines and opioids. A limitation of the study is that we lacked data on pH and base excess and could not evaluate the chronicity of the respiratory failure or the level of metabolic compensation. Nevertheless, the study presents data on the prognostic role of PaCO$_2$ in patients starting LTOT for COPD that are likely to be applicable to current clinical practice.

An interesting additional finding was the large variability in the change in PaCO$_2$ when starting LTOT. There is concern among clinicians that the level of PaCO$_2$ will increase after starting LTOT, especially in hypercapnic patients. In the present study, 30% of patients with hypercapnia actually decreased their PaCO$_2$ to below 6.5 kPa after initiation of LTOT and PaCO$_2$ remained unchanged in 36% of patients. This may be explained by regression to the mean and by improving blood gases over time in patients starting LTOT in relation to an exacerbation. The change in PaCO$_2$ between breathing room air and breathing oxygen (LTOT) did not predict mortality. This suggests that some increase in PaCO$_2$ from baseline when starting LTOT is well-tolerated and not associated with worse prognosis.

Which mechanisms underpin the association between blood gas disturbances and mortality? The lack of a clear association between P[A-a]O$_2$ and mortality implies that gas exchange inefficiency is not the main driver behind the increased mortality associated with hypoxemia and hypo- and hypercapnia. Our study suggests that the level of alveolar ventilation predicts mortality independently of the level of hypoxemia. Factors contributing to the increasing mortality could include more severe underlying COPD, respiratory maladaptation, and the presence of comorbidities. In hypocapnia, increased minute ventilation may cause respiratory muscle fatigue, hastened ventilatory failure and death. This might reflect a relative inability among these patients to adapt their breathing pattern to avoid respiratory muscle fatigue. Comorbidities such as congestive heart failure or pulmonary embolism may also contribute to the increased ventilation and worse prognosis. Modest hypercapnia may reflect an adaptive alveolar hypoventilation, which occurs (unconsciously) to minimize dyspnea and respiratory muscle fatigue. While modest hypercapnia were not associated with earlier death, PaCO$_2$ (air) exceeding 7.0 kPa seemed to be maladaptive and associated with increased mortality rates. Mechanical defects of the chest wall, such as kyphoscoliosis, and hyperinflation may predispose to alveolar hypoventilation by imposing additional work on the inspiratory muscles [30]. Concurrent hypoventilation syndrome may contribute to hypercapnia in some COPD patients, requiring treatment with home mechanical ventilation in addition to oxygen therapy [31]. However, it is still unclear whether long-term non-invasive home ventilation improves prognosis in patients with stable hypercapnic COPD [32].

![Figure 1 PaCO$_2$ and adjusted mortality in oxygen-dependent COPD.](image)

**Figure 1** PaCO$_2$ and adjusted mortality in oxygen-dependent COPD. Hazard ratio of death for different levels of PaCO$_2$ (air) compared to at PaCO$_2$ (air) = 6.5 kPa, adjusted for age, sex, PaO$_2$ (air), WHO performance status, BMI, number of cardiovascular diagnoses, and treatment with oral glucocorticoids, benzodiazepines and opioids. Abbreviations: PaCO$_2$ (air), Arterial blood gas tension of carbon dioxide on air; PaO$_2$ (air), Arterial blood gas tension of oxygen on air; WHO, World Health Organization; BMI, Body Mass Index.
For clinicians, this study suggests that patients with PaCO₂ (air) below 5 kPa or above 7 kPa are at increased risk of death and should be optimally treated and carefully followed. Furthermore, patients with hypo- or hypercapnia should be evaluated for comorbid diseases, including heart failure and hypoventilation syndromes. The U-shaped association of PaCO₂ (air) with overall mortality should be validated by further studies and incorporated in future prognostic models of patients with advanced COPD.

**Conclusion**

In conclusion, the level of alveolar ventilation, as reflected by both hypo- and hypercapnia, predicts mortality in oxygen-dependent COPD.
