Abstract

We report on In$_{0.55}$Ga$_{0.45}$As nanowire MOSFETs (NWFETs) with record performance in several key metrics for VLSI applications. These devices exhibit $I_{\text{ON}} = 555 \mu\text{A/\mu m}$ (at $I_{\text{OFF}} = 100 \text{nA/\mu m}$ and $V_{\text{DD}} = 0.5 \text{ V}$), $I_{\text{ON}} = 365 \mu\text{A/\mu m}$ (at $I_{\text{OFF}} = 10 \text{nA/\mu m}$ and $V_{\text{DD}} = 0.5 \text{ V}$) and a quality factor $Q \equiv g_m/SS$ of 40, all of which are the highest reported for a III-V as well as silicon transistor. Furthermore, a highly scalable, self-aligned gate-last fabrication process is utilized, with a single nanowire as the channel. The devices use a $45^\circ$ angle between the nanowire and the contacts, which allows for up to a 1.4 times longer gate length at a given pitch.

Introduction

In$_{x}$Ga$_{1-x}$As MOSFETs are expected to deliver high on-currents at a reduced $V_{\text{DD}}$ of 0.5 V, making them suitable for VLSI applications. This is due to their high mobility, which enables increased transconductance $g_m$ at a given $L_G$. For instance, we have recently demonstrated In$_{0.55}$Ga$_{0.45}$As NWFETs with $g_m = 3.3 \text{ mS/\mu m}$, surpassing that of all other III-V and silicon transistors, including HEMTs [4]. However, to achieve high $I_{\text{ON}}$ at a specified $I_{\text{OFF}}$ and $V_{\text{DD}} = 0.50 \text{ V}$ (an important VLSI metric) comparable to state-of-the-art silicon technology, the subthreshold slope must be near 60 mV/decade. This is challenging in III-V technology due to the oxide interface quality and small band gap, causing e.g. band-to-band tunneling in the off-state. Recently, planar InAs MOSFETs with $I_{\text{ON}}$ matching or surpassing that of silicon technology were reported [12]. In this work, we report on NWFETs with a new record of $I_{\text{ON}} = 555 \mu\text{A/\mu m}$ at $I_{\text{OFF}} = 100 \text{nA/\mu m}$ and $V_{\text{DD}} = 0.5 \text{ V}$.

Device Fabrication

Fig. 1 shows a schematic of the fabricated device, and the process flow. The nanowires are formed by selective area growth, using hydrogen silesquioxane (HSQ) as the MOCVD growth mask. The composition of the nanowire layer is In$_{0.65}$Ga$_{0.35}$As, while the nanowire is In$_{0.55}$Ga$_{0.45}$As, determined by EDX. Fig. 2(a)-(c) demonstrate the scalability of the selective growth process. A high-density nanowire-cluster with nanowire spacing of <10 nm is shown in fig. 2c. In this work, we characterize single-nanowire devices. The highly doped In$_{0.65}$Ga$_{0.35}$As ($N_D = 5 \times 10^{19} \text{ cm}^{-3}$) contact layer is formed from a subsequent MOCVD growth step using HSQ as a dummy gate [Fig. 2(d)]. A $45^\circ$ angle between the nanowire and the contacts is chosen in order to obtain optimal crystal facets. At a given pitch, this will also improve electrostatic control by allowing a longer gate length. After mesa isolation, Ti/Pd/Au is patterned and evaporated as the contact metal. The InP in the channel region is etched by HCl (1:1), in order for the metal to properly cover the sides of the nanowire. Several cycles of surface oxidation by ozone and diluted HCl etching is performed in order to reduce the dimensions of the nanowire. Surface passivation, by (NH$_4$)$_2$S (1:1) for 20 min, is followed by deposition of Al$_2$O$_3$/HfO$_2$ (EOT = 1.5 nm) by ALD at 300/100°C. Subsequently, an in-situ 12 hour post-deposition annealing step at 100°C in N$_2$ atmosphere is performed. Ni/Pd gate metal patterning and evaporation completes the process.

Results

Fig. 3(a)-(c) show subthreshold, transfer and output characteristics of an $L_G = 70 \text{ nm}$ NWFET with nanowire width and height $W_{\text{SW}}/H_{\text{SW}} = 25/7 \text{ nm}$. Peak transconductance is $g_m\text{peak} = 2.85 \text{ mS/\mu m}$. The subthreshold characteristics for the same device are shown in Fig. 4. The subthreshold slope (SS) is 80 mV/decade at both $V_{\text{DS}} = 0.5 \text{ V}$ and 50 mV. The drain-induced barrier-lowering (DIBL) is 43 mV/V at $I_{\text{DS}} = 1 \text{ \mu A/\mu m}$. The device exhibits $I_{\text{ON}} = 555 \mu\text{A/\mu m}$ at $I_{\text{OFF}} = 100 \text{nA/\mu m}$ and $V_{\text{DD}} = 0.5 \text{ V}$, which is the highest reported value for a MOSFET. The quality factor $Q \equiv g_m$/SS is 35 for this device. The on-resistance is $R_{\text{ON}} = 177 \text{ \Omega/\mu m}$ at $V_{\text{GS}} > 1.4 \text{ V}$. The specific contact resistivity is $\rho_c = 7 \times 10^{-4} \text{ \Omega cm}^2$ and the sheet resistance of the n$^+$ In$_{0.85}$Ga$_{0.15}$As contact layer is $R_s = 70 /\text{\Omega/\square}$. This is translated to TLM measurements.

Fig. 4 shows transfer characteristics for another $L_G = 70 \text{ nm}$ device with $g_m\text{peak} = 2.65 \text{ mS/\mu m}$ at $V_{\text{DS}} = 0.5 \text{ V}$. The average SS over one, two and three decades is 65, 69 and 73 mV/decade, respectively, all at $V_{\text{GS}} = 0.5 \text{ V}$. This device shows $I_{\text{ON}} = 535 \mu\text{A/\mu m}$ at $I_{\text{OFF}} = 100 \text{nA/\mu m}$ and $I_{\text{OFF}} = 365 \mu\text{A/\mu m}$ at $I_{\text{OFF}} = 10 \text{nA/\mu m}$, $V_{\text{DD}} = 0.5 \text{ V}$. This is the highest reported $I_{\text{ON}}$ at $I_{\text{OFF}} = 100 \text{nA/\mu m}$. DIBL is 56 mV/V at $I_{\text{DS}} = 1 \mu \text{A/\mu m}$. The quality factor $Q = g_m$/SS is 40 for this device, which is the highest reported Q-factor for a MOSFET. The difference in SS between these devices may be explained by the discrete nature of traps in the small channel area ($2 \times 10^{-3} \text{ \mu m}^2$).

The hysteresis (Fig. 5) is $\Delta V_T = 60 \text{ mV}$ for $V_{\text{GS}} = 0.2-1.0 \text{ V}$, indicating high-quality oxide and oxide interface. $I_{\text{OFF}}$ versus $I_{\text{ON}}$ for several devices with $L_G = 70 \text{ nm}$ and $W_{\text{SW}}/H_{\text{SW}} = 25/7 \text{ nm}$ is shown in Fig. 6, measured at a swing of $V_{\text{DD}} = 0.5 \text{ V}$. Fig. 7 shows SS versus $L_G$. Error bars show the standard deviation. SS and DIBL versus nanowire width $W_{\text{SW}}$ is shown in Fig. 8 ($H_{\text{SW}} = 7 \text{ nm}$). Data points are offset for clarity. Improved electrostatic control from use of smaller nanowires can clearly be observed. The trend indicates that SS can be further reduced by additional scaling down of $W_{\text{SW}}$. Fig. 9 and 10 show benchmarks of $I_{\text{ON}}$ and $Q$ for various planar and non-planar MOSFETs.

Conclusions

We have demonstrated highly scalable nanowire MOSFETs with record high performance in several key VLSI metrics. We have shown a device with $g_m = 2.85 \text{ mS/\mu m}$, $SS = 80 \text{ mV/decade}$ and $I_{\text{ON}} = 555 \mu\text{A/\mu m}$ at $I_{\text{OFF}} = 100 \text{nA/\mu m}$ and $V_{\text{DD}} = 0.5 \text{ V}$. We have also shown a device with $g_m = 2.65 \text{ mS/\mu m}$ and SS = 65 mV/decade, which gives a quality factor $Q = 40$.
