Global investigation and meta-analysis of the $C9orf72 \, (G_4C_2)_n$ repeat in Parkinson disease

**ABSTRACT**

**Objectives:** The objective of this study is to clarify the role of $(G_4C_2)_n$ expansions in the etiology of Parkinson disease (PD) in the worldwide multicenter Genetic Epidemiology of Parkinson’s Disease (GEO-PD) cohort.

**Methods:** $C9orf72 \, (G_4C_2)_n$ repeats were assessed in a GEO-PD cohort of 7,494 patients diagnosed with PD and 5,886 neurologically healthy control individuals ascertained in Europe, Asia, North America, and Australia.

**Results:** A pathogenic $(G_4C_2)_{60}$ expansion was detected in only 4 patients with PD (4/7,232; 0.055%), all with a positive family history of neurodegenerative dementia, amyotrophic lateral sclerosis, or atypical parkinsonism, while no carriers were detected with typical sporadic or familial PD. Meta-analysis revealed a small increase in risk of PD with an increasing number of $(G_4C_2)_n$ repeats; however, we could not detect a robust association between the $C9orf72 \, (G_4C_2)_n$ repeat and PD, and the population attributable risk was low.

**Conclusions:** Together, these findings indicate that expansions in $C9orf72$ do not have a major role in the pathogenesis of PD. Testing for $C9orf72$ repeat expansions should only be considered in patients with PD who have overt symptoms of frontotemporal lobar degeneration/amyotrophic lateral sclerosis or apparent family history of neurodegenerative dementia or motor neuron disease. *Neurology®* 2014;83:1906-1913

**GLOSSARY**

ALS = amyotrophic lateral sclerosis; FTLD = frontotemporal lobar degeneration; GEO-PD = Genetic Epidemiology of Parkinson’s Disease; PD = Parkinson disease; RP = repeat-primed; STR = short tandem repeat.

A substantial number of patients with frontotemporal lobar degeneration (FTLD)/amyotrophic lateral sclerosis (ALS) (14%–35%) carrying $C9orf72 \, (G_4C_2)_{>60}$ expansions Present with atypical parkinsonism in early disease stages and increased incidence of parkinsonism with or without features of the FTLD/ALS complex in their relatives. Ten research groups have reported on $C9orf72$ repeat expansions in Parkinson disease (PD) or atypical parkinsonism patients but none of these investigated the $C9orf72$ repeat in large-scale cohorts, and European and Australian populations were underrepresented in the published data. Apart from the pathogenicity of $(G_4C_2)_{>60}$ expansions, we provided in vitro evidence that the $(G_4C_2)_n$ repeat size negatively correlated with the transcriptional activity of the $C9orf72$ promoter. Hence, it is conceivable that an increasing number of $C9orf72$ repeats may affect transcription gradually and increase susceptibility to disease. Three studies indicated a role of $C9orf72$ repeats in PD susceptibility but associations were found using different dichotomizations of repeat length, muddling biological interpretation. In one study, a marginal increased risk of PD was observed for carriers of $(G_4C_2)_{>10}$ repeats. In the second, a significant increased frequency of $(G_4C_2)_{>20}$ repeats was observed in patients clinically diagnosed with PD. In the third study, the authors

Supplemental data at Neurology.org

Methods. Standard protocol approvals, registrations, and patient consents. Genetic studies applied in this research were approved by the ethics committees of the ZNA (Hospital Network Antwerp), the Antwerp University Hospital, and University of Antwerp. Clinical protocols were approved by the ethics committees of the ZNA, the Antwerp University Hospital, and local ethical review boards of the participating research centers. All human biological samples were collected, fulfilling ethical approvals, and used in accordance with the terms of subjects’ written informed consent.

Participants. The Genetic Epidemiology of Parkinson’s Disease (GEO-PD) Consortium includes investigators from 60 sites from 30 countries and 6 continents (http://www.GEO-PD.org/about/). All sites were invited to participate in this study. A total of 18 sites representing 12 countries and 4 continents contributed either DNA or genotypic data, and clinical data of in total 15,123 individuals (tables 1 and 2). After thorough quality control as described in the procedures section below, 13,669 samples were included in this study. We excluded all duplicate samples, sex mismatches, and samples that failed in the DNA fingerprint analysis because of low quantity or quality of DNA or because of contamination of the sample. Demographics and diagnostic criteria of each series included in this study and the sample size breakdown from each site are provided in table 2. Controls were collected at the local sites as demographically matched neurologically healthy individuals.

Procedures. Sample quality control. Concentration and purity were checked spectrophotometrically using the Trinean DropSense96 UUVIS droplet reader (Trinean, Genbrugge, Belgium) for all consortium genomic DNA samples. Sex and DNA fingerprint were determined for all samples using an in-house-developed multiplex PCR panel composed of 13 short tandem repeat (STR) markers distributed over multiple autosomal locations: D20S480, D22S1174, D5S1287, D3S1744, D5S1764, D7S872, D7S2426, D8S1746, D14S1005, D20S866, D10S1237, D20S912, and D6S965. This panel also includes a marker specific for the X chromosome (DXX1877) and one for the Y chromosome, and enables fast and accurate sample identification and sex determination in a single assay. After selective amplification of 20 ng genomic DNA, amplification products were size separated on an ABI 3730 automated sequencer (Applied Biosystems, Foster City, CA) using GeneScan-600 LIZ (Applied Biosystems) as internal size standard and genotypes were assigned using in-house–developed TracI genotyping software (http://www.vbgeneticsservicefacility.be).

Genetic analyses. To screen the GEO-PD cohorts for the pathogenic (G4C2)60 C9orf72 repeat expansion, we designed a 2-step procedure: an STR fragment length assay with flanking PCR primers optimized for alleles with high GC content (STR-PCR) followed by 2 repeat-primed PCR assays (forward and reverse RP-PCR) as described earlier.2,19 Four participating research groups performed the genotyping in their local facilities according to previously published procedures.2,19 For consistent allele scoring of repeat lengths between GEO-PD groups and accurate interpretation of the repeat length, we designed a reference DNA set of 14 samples covering a range of normal repeat sizes that was genotyped by each of these facilities. Furthermore, for 2 of the cohorts, a random set of samples homozygous for the STR-PCR assay were included in the RP-PCR analysis at the Antwerp site for independent validation of the absence of a pathogenic repeat expansion.

Statistical analyses. To investigate the association between repeat units and PD susceptibility, 3 explorative approaches were followed, based on (1) allele counts of the distinct repeat sizes, to determine whether one or more specific repeat sizes were associated with PD, (2) the total number of repeat units (sum of both alleles) per individual, and (3) the size of the longest repeat per individual (maximum allele). Summary statistics were computed in a random-effects meta-analysis (DerSimonian–Laird)21 for each approach in the mmeta package implemented in the R environment version 2.15.3. Based on the results obtained in the above-mentioned analyses, we performed hypothesis-driven dichotomized genotypic meta-analyses. Details are provided in the e-Methods on the Neurology® Web site at Neurology.org.

To take into account the number of tests performed (n = 22), a Bonferroni-corrected 2-sided p value of ≤0.002 was considered statistically significant. Population attributable risk of (G4C2)5–60, (G4C2)6–10 and (G4C2)10–17 was estimated using the epiR package in R. For the meta-analyses, only the cohorts including both the patients with PD and the controls that were

Abbreviations: AAO = age at onset; GEO-PD = Genetic Epidemiology of Parkinson’s Disease; NA = not available; PD = Parkinson disease; PI = principal investigator; QC = quality control; STR = short tandem repeat; UKPDBB = UK Parkinson’s Disease Brain Bank.

At the initial quality control step (QC), we excluded all duplicate samples, sex mismatches, and samples that failed in the DNA fingerprint analysis because of low quantity or quality of DNA or because of contamination of the sample. Additional samples did not pass the 2-step genetic analysis because of DNA shortage or limited concentration of the DNA sample.
The German patient was diagnosed with idiopathic PD at the age of 57 years. One year after onset, clinical examination revealed hypomimia, hypokinesia, resting tremor of the right arm, minor postural instability, mild bilateral rigidity, and slowed shuffling gait but also short-term memory disturbances, social withdrawal, and minor apathy. The patient had a positive family history of neurodegenerative dementia. All 3 French patients were diagnosed with PD without cognitive dysfunction at disease onset, and a detailed clinical description has been reported previously. Briefly, the first patient developed left hemiparkinsonism at age 29 years and symptoms worsened progressively while dopamine agonists were only partially effective. In the second patient, parkinsonism began at age 48 years and a cognitive decline was noted at age 56 years. The third patient developed parkinsonism at age 64 years and developed a mild cognitive deficit at age 69. Although these 3 patients were clinically diagnosed with PD, they all had familial histories of atypical parkinsonism, degenerative dementias, or ALS. No expansions were detected in patients with sporadic PD or patients with a familial history of PD. Moreover, mutations in known PD genes had previously been excluded in these 4 pathogenic expansion carriers.

We identified one Asian control of Chinese origin with an age at inclusion of 52 years carrying a pathogenic (G₄C₂)₆₀ expansion (table 1). Currently, there is no record of any symptoms related to PD, FTLD, or ALS in this individual. This brings the estimated prevalence of pathogenic repeat expansions in controls to 0.02% (1/5,478). Apart from the expansion mutations, the distribution of repeat lengths ranged from 0 to 32 in the Caucasian and from 7 to 14 in the Asian control persons.

C9orf72 repeat and PD susceptibility. We investigated the role of (G₄C₂)₉₆ repeats in risk of PD. First, we assessed the distribution of the alleles in patients with PD vs controls in the GEO-PD cohort (figure 1). The frequencies of the (G₄C₂)₁₀ allele and of (G₄C₂)₆₇ were nominally increased in PD vs the controls but the differences were not statistically significant after Bonferroni correction (figure 1, table 3, figure e-1, A and B). Genotypic frequencies for (G₄C₂)₁₀ (table 3, figure e-1, C) and (G₄C₂)₆₇ (table 3, figure e-1, D) were not significantly different between patients and controls after correction for multiple testing. The estimated attributable fractions in the population are very low (table 3). When considering the sum of the alleles and the size of the maximum allele as a quantitative variable, we observed a small but significant increase of disease risk with a rising number of repeat units (sum of alleles p = 0.0012, summary effect [B] = 0.0128 [0.0050–0.0205], figure e-2, A; maximum allele p = 0.0010, summary effect [B] = 0.0181 [0.0073–0.029], figure e-2, B). Together, these results suggested that the risk effect may not only be linked to the (G₄C₂)₁₀ repeat but may be increasing with length while the effect in the larger alleles is probably masked by the small number of carriers. Therefore, we decided to analyze the risk effect of C9orf72 repeat expansions as a binary categorical value with a cutoff between 9 and 10. However, neither allelic nor genotypic meta-analysis of the GEO-PD cohorts revealed significant association with PD for (G₄C₂)≥10 repeat alleles after Bonferroni correction (table 3, figure e-3, A and B). Furthermore, the estimated population attributable risk is low (table 3).

DISCUSSION Molecular reclassification of complex brain diseases based on genetic etiology is of utmost importance to improve differential diagnosis and to rationalize drug development. Assessment of the contribution of novel disease genes to clinically and pathologically overlapping diseases is instrumental in this reclassification. In this global study, we assessed the prevalence of (G₄C₂)₉₆ repeats and expansions in an extended PD cohort ascertained within the GEO-PD Consortium and excluded a major role for pathogenic (G₄C₂)≥6₀ repeat expansions in the causation of PD. The low frequency of these expansions (0.06%) in the GEO-PD cohort is in agreement with earlier findings in distinct patient groups10,15,16,19 and falls in the range of frequencies observed in controls by us (0.02%) and others (0–0.6%).14,22 Furthermore, 75% of the pathogenic expansion carriers in this global study showed a decline in cognitive functions within 1 to 8 years after onset. In the absence of autopsy diagnoses, we therefore cannot exclude that some if not all of these expansion carriers are primarily FTLD/ALS patients with pronounced early parkinsonian symptoms or comorbidity of PD and FTLD/ALS. This hypothesis is supported by the identification of only one pathogenic mutation carrier.
in 826 (0.1%) autopsy-confirmed PD cases. Of note, this carrier presented, in addition to Lewy body pathology, with frontotemporal degeneration and C9orf72-ALS/FTLD pathology with numerous p62-positive inclusions. Furthermore, although substantia nigra involvement is common in C9orf72-positive ALS, it can be clearly distinguished from PD-related mechanisms by the presence of p62-positive inclusion and absence of Lewy body pathology.

Altogether, it is not advisable to include C9orf72 (G4C2)n repeat expansion testing in a medical genetic diagnostic setting for typical PD patients. Exceptions can be made for patients with PD who have cognitive and/or behavioral deficits early in the disease process or in patients with a personal or familial history of FTLD/ALS. Given differences in the existing literature on C9orf72 (G4C2)n repeat length as risk factor for PD, we used the size of this global cohort to estimate a PD-related threshold of C9orf72 repeats. Calculation of the risk for each of the observed C9orf72 (G4C2)n alleles in the GEO-PD cohorts suggested a role for the 10-units repeat and for the pooled alleles of 17 units or more in PD susceptibility. Genotypic meta-analysis supported a possible link between (G4C2)10 and increased risk of PD but the association did not reach significance after correction for multiple testing. In addition, the number of carriers of these intermediate alleles is small and one should be cautious with the interpretation of these results. Furthermore, it is difficult to envisage the biological relevance of risk associated with a single

For the meta-analyses, only the cohorts including both patients with Parkinson disease and geographically matched controls that were size-corrected using the reference panel were included. The p values were calculated using DerSimonian-Laird meta-analysis; p = .002 is considered statistically significant [22 tests].

*Allele count approach.

Dichotomized approach.

Of note, we observed a small but significant increase in risk with an accumulative number of repeats supporting the idea of a threshold size rather than a single allele as the culprit of increased risk. We therefore decided to study the combined effect of (G₄C₂) alleles of 10 units and larger in the global GEO-PD cohort. Although meta-analyses implicated a potential role for these intermediate-sized repeats in PD risk, none of the associations survived Bonferroni correction suggesting that if C9orf72 repeats of 10 units or larger have a role in PD susceptibility, the effect is small. This is supported by the fact that none of the published genome-wide association studies revealed the C9orf72 locus as a risk factor for PD.25 A limitation of this study is that we did not yet include all published association studies of C9orf72 in PD; however, we chose to include only those studies that were corrected for allele scoring bias based on a reference panel.

Altogether, these data support the current hypothesis that pathogenic (G₄C₂)ₙ repeat expansions in C9orf72 appear to be specific for the FTLD/ALS spectrum with little or no contribution to the wider spectrum of movement disorders. It will be of interest to study the role of intermediate repeats ≥10 units in other neurodegenerative disorders, however, to obtain a more profound knowledge on their role in neurodegenerative diseases and a better understanding of the underlying mechanism.

AUTHOR CONTRIBUTIONS

Josie Theuns: drafting and revising the manuscript for content, study concept and design, analysis and interpretation of data, acquisition of data, statistical analysis, study supervision and coordination, obtaining funding. Aline Verversnen: revising the manuscript for content, study design, analysis and interpretation of data, acquisition of data, statistical analysis, study coordination. Kristel Sleegers: drafting and revising the manuscript for content, study concept, analysis and interpretation of data, statistical analysis, obtaining funding. Eline Wauters: revising the manuscript for content, analysis and interpretation of data, acquisition of data. Stefanie Smolders: revising...
the manuscript for content, analysis and interpretation of data, acquisition of data. David Cross: revising the manuscript for content, analysis and interpretation of clinical data, acquisition of clinical data, contribution of vital reagents. Ellen Casimir: revising the manuscript for content, analysis and interpretation of data, acquisition of data. Reijo Krüger: revising the manuscript for content, analysis and interpretation of data, acquisition of data. Suzanne Leug: revising the manuscript for content, acquisition of data, analysis and interpretation of data, contribution of vital reagents, local study coordination. Alexis Brié: revising the manuscript for content, acquisition of clinical data, contribution of vital reagents, local study supervision. Sun Ju Chung: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Young Jin Kim: revising the manuscript for content, acquisition of clinical data, contribution of vital reagents, local study supervision. Mi-Jung Kim: revising the manuscript for content, acquisition of clinical data, contribution of vital reagents. Zbigniew K. Wszolek: revising the manuscript for content, analysis and interpretation of clinical data, acquisition of clinical data, contribution of vital reagents. Ekaterina Rogaeva: revising the manuscript for content, analysis and interpretation of data, acquisition of data, contribution of vital reagents. Zhongui Xu: revising the manuscript for content, analysis and interpretation of data, acquisition of data. Anthony E. Lang: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Christine Klein: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Anne Weisbach: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Pototo Ogaki: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Eng-King Tan: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Yi Zhao: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Jan Audy: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Enza Maria Valente: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Simona Peruccci: revising the manuscript for content, acquisition of clinical data, contribution of vital reagents. Grazia Amnes: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Aldo Quattrone: revising the manuscript for content, acquisition of clinical data, contribution of vital reagents. Carlo Ferrarese: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Andrea Pischmann: revising the manuscript for content, acquisition of clinical data and biospecimen, contribution of vital reagents, local study design, obtaining funding for local site. Chister Nilsson: revising the manuscript for content, acquisition of clinical data, contribution of vital reagents. Mark S. LeDoux: revising the manuscript for content, acquisition and interpretation of clinical data and biospecimen, contribution of vital reagents. Ronald F. Pfeiffer: revising the manuscript for content, acquisition of clinical data, contribution of vital reagents. Magdalena Bozacka-Jedynek: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of data, acquisition of data. Ellen Elinck: revising the manuscript for content, analysis and interpretation of data, acquisition of data. Reijo Krüger: revising the manuscript for content, analysis and interpretation of data, acquisition of data. Suzanne Leug: revising the manuscript for content, acquisition of data, analysis and interpretation of data, contribution of vital reagents, local study coordination. Alexis Brié: revising the manuscript for content, acquisition of clinical data, contribution of vital reagents, local study supervision. Sun Ju Chung: revising the manuscript for content, acquisition of clinical data, analysis and interpretation of clinical data, contribution of vital reagents. Peter Paul De Deyn: revising the manuscript for content, local study design, acquisition of clinical data, contribution of vital reagents, local study supervision. Patrick Cras: revising the manuscript for content, local study design, acquisition of clinical data, interpretation of clinical data, contribution of vital reagents, local study supervision. Marc Cross: drafting and revising the manuscript for content, study concept and design, analysis and interpretation of data, study supervision or coordination, obtaining funding. Christine Van Broeckhoven: drafting and revising the manuscript for content, study concept and design, analysis and interpretation of data, contribution of vital reagents/tools/patents, statistical analysis, study supervision or coordination, obtaining funding.

ACKNOWLEDGMENT

Belgium: The authors thank the VIB DMG Genetic Service Facility (http://www.vibgeneticsservicefacility.be) for technical assistance. Italy-Cosenza: The authors thank Patrizia Tarantini, Institute of Molecular Bioimaging and Physiology, National Research Council, Section of Germaneto (CZ), Italy and Monica Gaglardi, Institute of Molecular Bioimaging and Physiolog, National Research Council, Section of Germaneto (CZ), Italy and Institute of Neurology, Department of Medical Sciences, University Magna Graecia, Catanzaro, Italy.

STUDY FUNDING

Belgium-Antwerp: The research is in part funded by the Belgian Science Policy Office Interuniversity Attraction Poles (IAP) program; the European Initiative on Centers of Excellence in Neurodegeneration (CoDEN); the Flemish Government initiated Methusalem Excellence Program; the Alzheimer Research Foundation (SAO/FRF); the Queen Elisabeth Medical Foundation (QEMF); the Research Foundation Flanders (FWO); the Agency for Innovation by Science and Technology Flanders (IWT); the University of Antwerp Research Fund, Belgium; and the MerLife Foundation for Medical Research Award to C.v.B. The IWT provided a PhD fellowship to A.V. and E.W. and the FWO a postdoctoral fellowship to I.G. The authors acknowledge the personnel of the Genetic Service Facility of VIB (http://www.vibgeneticsservicefacility.be) and the Antwerp Bionbank of the Institute Born-Bunge for their expert support. France: The authors thank the French Parkinson’s Disease Genetics Study Group, Y. Agid, M. Anheim, A.-M. Bonnet, M. Borg, A. Brice, E. Broussolle, J.-C. Corvol, P. Damier, A. Destee, A. Diur, F. Daraf, S. Klébe, P. Krak, E. Lohmann, M. Martínez, P. Polik, O. Rasol, F. Tron, C. Tranchant, M. Yrim, P. Vialet, and M. Vidalhiet; Franco-Parkinson Association and the French program “Investissements d’avenir” funding (ANR-10-IAIHU-06). USA-Florida: Mayo Clinic Florida is a Morris K. Udall Center of Excellence in PD Research. Mayo Research (to Manu Sharma). This work has also been made possible by the kind support of the Michael J. Fox Foundation, Mayo Clinic Center for Regenerative Medicine, and a gift from Carl Edward Bolch, Jr., and Susan Bass Bolch. Canada: W. Garfield Weston Foundation and Ontario Research Fund (E.R.). Germany-Luebeck: C.K. is supported by a career development award from the Hermann und Lilly Schilling Foundation. Germany-Tuebingen: The KORA (Cooperative Research in the Region of Augsburg) research platform was started and financed by the Forschungszentrum fur Umwelt und Gesundheit, which is funded by the German Federal Ministry of Education, Science, Research, and Technology and by the State of Bavaria. This work has also been made possible by the kind support of the Michael J. Fox Foundation (MJP) for Parkinson’s Research (to Manu Sharma). This study was also funded by the German National Genome Network.
DISCLOSURE

The authors report no disclosures relevant to the manuscript. Go to Neurology.org for full disclosures.

Received May 8, 2014. Accepted in final form August 13, 2014.
