(Received 4 February 2014; accepted 25 February 2014; published online 7 March 2014)

Terahertz absorption spectra have been recorded for the weakly bound CO$_2$–H$_2$O complex embedded in cryogenic neon matrices at 2.8 K. The three high-frequency van der Waals vibrational transitions associated with out-of-plane wagging, in-plane rocking, and torsional motion of the isotopic H$_2$O subunit have been assigned and provide crucial observables for benchmark theoretical descriptions of this systems’ flat intermolecular potential energy surface. A (semi)-empirical value for the zero-point energy of 273 ± 15 cm$^{-1}$ from the class of intermolecular van der Waals vibrations is proposed and the combination with high-level quantum chemical calculations provides a value of 726 ± 15 cm$^{-1}$ for the dissociation energy $D_0$. © 2014 AIP Publishing LLC, [http://dx.doi.org/10.1063/1.4867901]

The intermolecular interaction between CO$_2$ and H$_2$O plays a major role for a variety of phenomena in physics, chemistry, and biology including the radiative transfer through the Earth’s and other planetary atmospheres,$^1$ the early stages in carbonic acid formation$^2$ and the transportation of dissolved CO$_2$ in the tissues of biological organisms. The prototypical binary mixed van der Waals complex of CO$_2$ and H$_2$O has been intensively investigated by both theory and experiment. Numerous quantum-chemical studies of the systems’ intermolecular potential energy surface (IPES) have been reported.$^3$–$^{13}$ High level of electron correlation, extensive basis sets, and inclusion of basis set superposition errors prove mandatory as the IPES is extremely flat near the global potential energy minimum. A recent comprehensive work reports a complete 5D $ab$ initio IPES composed of 23 000 high level single-point energies in configuration space and settles that the global potential energy minimum has a planar and T-shaped geometry of C$_2v$ symmetry with the oxygen atom of H$_2$O bound to the C atom and the H atoms pointing away from the CO$_2$ molecule$^{14}$ (Fig. 1). This global potential energy minimum geometry has independently been confirmed experimentally by a variety of spectroscopic studies$^{15}$–$^{17}$,27 whereas other works have suggested the existence of other higher energy configurations.$^{18}$–$^{19}$ The most important observable is the dissociation energy $D_0$ which requires reliable band origins for the system’s complete set of fundamental vibrational transitions and in particular for the class of five intermolecular van der Waals vibrational transitions addressed in the present work.

Neon (L’Air Liquide, 99.5%) doped with CO$_2$ (Matheon, 99.9%) and degassed samples of H$_2$O, H$_2^{18}$O (Sigma Aldrich, 99.0% $^{18}$O) and D$_2$O (Sigma Aldrich, 99.5% D) with mixing ratios of $\pm 0.5%e$ to $5%e$ were deposited with a flow rate of 0.02 mol/h at 3.6 K on a gold-plated oxygen-free high thermal conductivity (OFHC) copper mirror inside an immersion helium cryostat (IHC-3) modified for matrix isolation spectroscopy at MAX-lab.$^{20}$ A 3-mm deep cavity with 10-mm diameter and a flat bottom has been drilled into the mirror centre to allow deposition of several millimeter thick matrices doped with weak absorbers. The mirror temperature was monitored by a Lake Shore silicon diode and maintained stable at 2.8 ± 0.1 K before and after deposition employing resistive heaters and feedback electronics. The sample mount was equipped with interchangeable CsI and polymethylpentene (TPX) windows and combined IR and THz single-beam spectra were collected by a Bruker IFS 120 FTIR spectrometer employing a globar lamp as radiation source. A HgCdTe detector combined with a Ge/KBr beam splitter and a Si-bolometer operating at 4.2 K combined with a 6 $\mu$m multilayer Mylar beam splitter were employed for the IR and THz spectral regions, respectively. Spectral resolutions of 0.1–1 cm$^{-1}$ were selected depending on the observed bandwidths.

Figure 2 shows a series of THz absorption spectra collected for several millimeter thick cryogenic neon matrices doped with CO$_2$ (CO$_2$:H$_2$O:Ne=1:0:800), H$_2$O (0:1:4000), and mixtures of CO$_2$ and H$_2$O (3:1:4000), respectively. A

dominant spectral feature observed for the matrices doped with regular H2O is observed at 79.5 cm$^{-1}$. This band has previously been assigned to a rotational-translation-coupling (RTC) transition of H2O monomer in neon and helps to monitor the H2O monomer concentration. At higher H2O concentrations, signs of hydrogen-bonded dimers of water started to show up. The strongest intermolecular hydrogen bond vibrations of (H2O)$_2$ observed in the THz region, the acceptor torsional and acceptor wagging modes, have previously been observed and assigned in neon matrices at 116.0 cm$^{-1}$ and 122.2 cm$^{-1}$.

THz spectra recorded for neon matrices doped solely with CO2 showed no signs of CO2-containing cluster entities in agreement with high-level theoretical studies of the weakly bound (CO2)$_2$ system. As shown in Fig. 2 the simultaneous use of CO2 and H2O as dopants allowed the identification of two new distinct bands located at 101.6 and 166.6 cm$^{-1}$; the latter band being a factor of 3–4 less intense. The intensity of these bands increased similarly with the CO2 and H2O concentration suggesting the assignments to a mixed (CO2)$_n$–(H2O)$_m$ complex. A stoichiometric 1:1 relationship could be confirmed at the low sample concentrations and by the complementary IR spectral series. THz spectra collected for neon matrices doped with CO2 and isotopically enriched samples of H$_2^{18}$O and D$_2$O/HDO are useful to validate the proposed assignments further. An illustrative spectrum obtained for CO2/H$_2^{18}$O doped neon matrices is shown in Fig. 2. The small isotopic shifts upon $^{18}$O-substitution have been reported previously both for the monomeric RTC transition and the strongest dimeric hydrogen bond vibrations of water.

The observed spectral shifts caused by the $^{18}$O-substitution are also very small for both the proposed CO2–H2O bands. The band at 101.6 cm$^{-1}$ seems to be rather unaffected by the $^{18}$O-substitution. The upper band has a small but significant reproducible isotopic red-shift of 1.9 cm$^{-1}$ as indicated by arrows in Fig. 2. The effect of deuteration has a much larger impact on the recorded THz spectra since both the monomeric and dimeric water spectral features have significant isotope shifts not to mention that mixed isotopic entities start to build up. Both the D2O and HDO as well as the mixed deuterated dimeric entities of water have been extensively studied previously and the complete list of spectral assignments is given in Table I. In the further spectral analysis of the isotopically enriched spectral signatures we consult quantum chemical predictions.

As described and cited in the introduction, a variety of high-level quantum chemical calculations have been performed to describe the accurate IPES of the CO2–H2O complex in great detail. In Table II, we have listed harmonic MP2/aug-cc-pVQZ predictions for the global potential energy

**FIG. 2.** A series of THz absorption spectra of 1.0 cm$^{-1}$ resolution collected for cryogenic neon matrices doped with CO2, H2O, and 3:1 mixtures of CO2 and isotopically enriched samples of H2O at 2.8 K. The CO2–H2O assignments are indicated by animated normal vibrations.
minimum with $C_{2v}$ symmetry. These predictions are in accordance with the study by Makarewicz$^{14}$ and specify the class of five intermolecular van der Waals vibrational transitions. The out-of-plane H$_2$O wagging mode $\nu_8$ ($B_2$) described by the intermolecular coordinate $\beta$ (Fig. 1) has a high intensity whereas the in-plane rocking of H$_2$O $\nu_{11}$ ($B_2$) described by $\alpha$ and the CO$_2$ librational rocking mode of $\nu_{12}$ ($B_2$) described by $\beta$ both have medium intensity. The H$_2$O torsional mode $\nu_6$ ($A_2$) described by $\gamma$ is strictly IR-forbidden for the regular CO$_2$–H$_2$O complex and the intermolecular O···C stretching mode $\nu_5$ ($A_1$) described by $r$ has a very low intensity. A convincing correlation immediately appears between the harmonic predictions and the observation of the two distinct bands at 101.6 and 166.6 cm$^{-1}$ for THz spectra of neon matrices doped simultaneously with CO$_2$ and H$_2$O. This excellent agreement between experiment and theory suggests straightforward assignments for the out-of-plane H$_2$O wagging mode $\nu_8$ at 101.6 cm$^{-1}$ and the in-plane H$_2$O rocking mode $\nu_{11}$ at 166.6 cm$^{-1}$ for the regular CO$_2$–H$_2$O complex. This agreement could partly be due to some kind of fortunate cancelation of smaller spectral shifts in opposite directions originating from anharmonicity effects and minor matrix perturbations which shall be discussed below. Small isotopic red-shifts are expected upon $^{18}$O-substitution on the water subunit since both these intermolecular vibrational modes involve hindered rotational motion of H$_2$O. The harmonic calculations for the enriched CO$_2$–H$_2^{18}$O system predict a very small red-shift of 0.9 cm$^{-1}$ for the H$_2$O wagging mode $\nu_8$ and a more pronounced red-shift of 2.2 cm$^{-1}$ for the H$_2$O rocking mode $\nu_{11}$ (Table III). These red-shift predictions are convincingly close to the observations within the experimental reproducibility. The predicted relative harmonic band intensity agrees qualitatively with the experimental findings. The rotational motion of D$_2$O is much slower relative to H$_2$O and rather large isotopic spectral red-shifts for both the D$_2$O wagging and rocking modes are expected. The harmonic calculations for CO$_2$–D$_2$O accordingly predict red-shifts of 24.3 and 19.1 cm$^{-1}$ with factors of 2 and 3 smaller harmonic band intensities, respectively, for these intermolecular van der Waals modes (Table III). The band origin for the strongest D$_2$O wagging mode is expected at 77.4 cm$^{-1}$ and thereby unavoidably overlapped with the strong RTC transitions for H$_2$O, HDO, and D$_2$O (Table I). The band origin for the D$_2$O rocking mode with medium intensity is predicted at 148.5 cm$^{-1}$ but the threefold loss of band intensity (8.5 km/mol) and the experimental challenge with isotopic H/D exchange and formation of HDO in the matrix inlet system was expected to blur this spectral signature. Nevertheless, a series of THz spectra recorded for neon matrices doped with CO$_2$/HDO/D$_2$O mixtures reproduces a medium strong band at 145.1 cm$^{-1}$ which we assign to the D$_2$O rocking transition of the CO$_2$–D$_2$O complex as indicated in Fig. 2. The rotational motion of HDO is slower relative to H$_2$O but faster relative to D$_2$O and smaller predicted isotopic spectral red-shifts for the H$_2$O wagging and rocking modes of 18.1 and 11.6 cm$^{-1}$, respectively, for CO$_2$–HDO relative to CO$_2$–H$_2$O are both expected. The harmonic band intensities are both predicted to be a factor of 2 smaller for this isotopic variant of the complex. The band origin for the stronger HDO wagging mode predicted at 83.6 cm$^{-1}$ cannot be observed unambiguously due to the overlapping RTC transitions of H$_2$O, HDO, and D$_2$O. The red-shifted HDO rocking mode predicted at 156.0 cm$^{-1}$ with 14.5 km/mol intensity is easily observed and assigned at 152.1 cm$^{-1}$ for the CO$_2$/HDO/D$_2$O doped neon matrices.

This assignment is indicated in Fig. 2 for an experiment with a CO$_2$:D$_2$O:HDO:H$_2$O composition of (18:6:6:1). The harmonic calculations of CO$_2$–HDO predict that the HDO torsional mode becomes IR-active. A band origin for the IR-forbidden H$_2$O torsional mode is predicted at 151.2 cm$^{-1}$ for regular CO$_2$–H$_2$O and red-shifted to 135.9 cm$^{-1}$ with significant intensity for the isotopic CO$_2$–HDO variant of $C_1$ symmetry. The spectral series of CO$_2$/HDO/D$_2$O doped neon matrices confirms another weaker band at 128.4 cm$^{-1}$ (Fig. 2) which does not show up in neon matrices doped solely with HDO/D$_2$O. This indirect and so far tentative assignment for the IR-forbidden H$_2$O torsional mode $v_6$ for the regular CO$_2$–H$_2$O complex requires extra attention in the discussion of this transition’s contribution to the zero-point energy.

The present experimental findings for the weakly bound CO$_2$–H$_2$O system enable us to provide a (semi)-empirical estimate of the system’s zero-point energy. The weakly bound nature of the CO$_2$–H$_2$O system results in rather small perturbations of the intramolecular vibrational transitions. The total shift of the zero-point energy contribution to $D_0$ caused by perturbations of intramolecular vibrational transitions is in the order of 5 cm$^{-1}$. A reliable determination of the system’s zero-point energy thus relies completely on accurate band origins for the set of five intermolecular van der Waals vibrational transitions introduced by complex formation. According to our harmonic MP2 predictions, the three observed transitions constitute about 75% of the total intermolecular vibrational zero-point energy contribution to the dissociation energy $D_0$. The contributions from the H$_2$O wagging mode $v_8$ observed at 101.6 cm$^{-1}$ and the H$_2$O rocking mode $v_{11}$ observed at 166.6 cm$^{-1}$ are clear. In order to establish the contribution from the IR-forbidden H$_2$O torsional mode $v_6$ we consider the effect of H/D substitution on this kind of motion. The torsional mode can be described as a hindered rotation of H$_2$O around the $C_2$ symmetry axis which also has the role of the principal $b$-axis for an isolated H$_2$O molecule. The torsional mode can as such be described as an almost genuine $b$-type rotation of H$_2$O although this motion is hindered in the complex. In the harmonic approximation the ratio of the two harmonic torsional band origins is thus proportional to the square root of the ratio of the $B$ rotational constants for the two isotopic water molecules in question. In this way, the use of experimental $B$-values predicts an isotopic harmonic red-shift of 21% for the band origin upon a single H/D-substitution. The model predicts a blue-shift of the proposed HDO torsional band origin at 128.4 cm$^{-1}$ to 166.1 cm$^{-1}$ for the corresponding IR-forbidden mode of the regular CO$_2$–H$_2$O system where our MP2 predictions provide a band origin close of 151.2 cm$^{-1}$. A complete unambiguous assignment of the HDO torsional cannot be justified solely by this crude model although the model provides a convincing argument. In our estimate for the zero-point energy we add a contribution of $75 \pm 5$ cm$^{-1}$ from this IR-forbidden mode. The band origin of the medium intense CO$_2$ librational mode $v_{12}$ predicted to 16.8 cm$^{-1}$ is close to the optical bandpass of our experimental setup and cannot be observed. In consequence, the zero-point energy contributions from this transition and the weak intermolecular O···C stretching transition $v_3$ are based on the theoretical values listed in Table II. We estimate a total (semi)-empirical contribution to the zero-point energy from the class of intermolecular van der Waals transitions to $273 \pm 15$ cm$^{-1}$ based on the present findings. A total zero-point energy contribution of $278 \pm 15$ cm$^{-1}$ is achieved by inclusion of the predicted contribution caused by perturbations of the intramolecular vibrational transitions.

The excellent agreement between our harmonic MP2 predictions and the observed band origins of CO$_2$–H$_2$O embedded in solid neon matrices is rather surprising. Harmonic predictions usually overshoot the actual (anharmonic) band origins for large-amplitude vibrational modes associated with intermolecular van der Waals transitions of weakly bound cluster molecules. A recent review addressing complexes of H$_2$O embedded in neon matrices reports that large-amplitude intermolecular vibrational transitions tend to be slightly blue-shifted relative to the gas phase although numerous red-shifts have been reported as well. These small blue-shifts of large-amplitude vibrations are ascribed as minor repulsive steric effects originating from the congested neon host environment. These combined arguments could suggest that both our harmonic predictions and observed neon matrix band origins are slightly higher than expected gas-phase values. The present experimental findings thus invite for future high-level anharmonic theoretical investigations of the large-amplitude vibrational CO$_2$–H$_2$O motion which may shed light on the subtle balance of potential neon matrix blue-shifts and anharmonicity effects for this weakly bound system. We consider as such our current (semi)-empirical estimate of $273 \pm 15$ cm$^{-1}$ as an upper limit for the intermolecular part of the zero-point energy. In the recent comprehensive theoretical study of the CO$_2$–H$_2$O system the highest level of theory including the almost complete electron correlation effects captured by the CCSD(T) approach and basis set superposition errors predicts an equilibrium dissociation energy $D_e$ of 1004 cm$^{-1}$. The combination with the present experimental findings thus provides a lower limit of $726 \pm 15$ cm$^{-1}$ for the dissociation energy $D_0$ for this prototypical van der Waals interaction.
