Introduction

It has traditionally been assumed that adjunct clauses are strong islands for extraction across languages, including in English (the Adjunct Condition, Huang, 1982). However, recent studies have claimed that extraction from adjunct clauses is possible in English given certain conditions.

Semantic coherence:
Extraction from adjunct clauses is possible in English, provided that a coherence relation (e.g., a causal, as opposed to a purely temporal relation) holds between the events referred to by the matrix and the adjunct clause (1a vs. 1b) [Truswell, 2011; Tanaka, 2015].

(1a) Who did John get upset [after talking to J?] (Truswell, 2011: 129)

Finiteness:
It has been argued that in English extraction from coherent adjuncts is only possible if the adjunct is non-finite (2a vs. 2b) [Truswell, 2011].

(2a) Who did John go home [after talking to J?]
(2b) Who, did John go home [after he talked to J?]

If coherence and/or finiteness indeed have an impact on the accessibility and/or processing of extraction from adjunct clauses, then we would need to determine if the remaining extraction potential is limited by either coherence or finiteness. Therefore, we examined the effects of coherence (i.e., causal vs. temporal) and finiteness (i.e., finite vs. non-finite) in Experiment 1.

The current study

The current study investigates how coherence and finiteness affect the acceptability (Exp. 1) and the real-time processing (Exp. 2) of adjunct island extraction in English.

Hypotheses:
- Predicted main effect of coherence: For Experiment 1, a higher level of sentential coherence will increase the accessibility of extraction from the adjunct as measured via higher ratings for coherent structures. For Experiment 2, higher coherence is expected to facilitate reading times at the embedded adjunct verb (R9) and spillover region (R10) where dependency formation is expected to occur.
- The presence of finiteness on the adjunct verb is expected to degrade the accessibility of extraction (Exp. 1) and slow processing at the adjunct verb (Exp. 2), provided that sentences are coherent – with no additional effect being hypothesized for non-coherent structures.

Finding an influence of either factor on dependency formation could be taken as evidence of the online permeability of such structures.

Experiment 1 (Acceptability judgments)

Participants: 72 mono-lingual, native English speakers.

Materials: 40 sentence items bearing argument extraction in the form of question formation (Which NP) from an after-adjunct clause, manipulating Coherence and Finiteness (3), distributed across four lists with 8 distractor items.

Procedure:
- 7-point Likert scale rating task (1 = “completely unacceptable” to 7 = “completely acceptable”) presented online using Google forms.

Results

Linear mixed models analysis: Main effect of Coherence: coherent > non-coherent (β = 0.283, t = 3.98, p = .001); Main effect of Finiteness: non-finite > finite (β = -0.095, t = -2.70, p < .05); Coherence × Finiteness interaction: finite < non-finite for coherent structures (β = -0.056, t = -2.60, p < .05).

Discussion

- Overall, ratings were on the low side of the scale, suggesting that extraction is difficult.
- The acceptability of extraction from adjunct islands is increased in the presence of a coherent relation between matrix and adjunct clause event.
- Finiteness reduces the acceptability of coherent structures in English.
- The small size of the finiteness effect points towards a processing phenomenon.

Figure 1. Exp. 1 stroked mean acceptability ratings

Experiment 2 (Self-paced reading)

Participants: 60 mono-lingual, native English speakers.

Materials: 40 critical sentences partially modified from those used in Experiment 1, rotated across four presentation lists. 8 distractor items.

Procedure:
- Word-by-word reading using E-Prime 3.0
- Twenty-five percent of the sentences were followed by a yes/no comprehension question

Results

Linear mixed models analysis of log residualised reading times for regions R5-R10 (excluding R8).

Discussion

- The absence of coherence is discovered already at the matrix.
- Overall faster reading times for coherent adjuncts compared to non-coherent adjuncts.
- A coherence effect and in coherent adjuncts a finiteness-related slowdown at regions associated with gap integration.
- → Coherence and an absence of finiteness facilitate processing and dependency formation in adjunct islands.
- The trending interaction between the coherence and finiteness factor at the wrap-up region suggests that finiteness might only affect later stages of integration in the coherent conditions (supported by the results from the pairwise comparisons).

Figure 2. Exp. 2 residualised reading times (ms) by condition and region (C = coherent, NC = non-coherent, F = finite, NF = non-finite)

General discussion

Findings:
- Overall, coherent structures involving dependency formation into an adjunct are rated higher than non-coherent structures and are processed faster at the regions where filler-gap integration is expected to occur.
- Finiteness decreases the acceptability of coherent extraction, but has no effect on non-coherent extraction.
- Finiteness increases processing time at the first point of filler-gap integration (the adjunct verb). However, finiteness appears to only affect coherent structures at later stages of integration (the wrap-up region).
- Later stages of integration during processing thus correspond to the offline acceptability ratings.

The Adjunct Condition:
The acceptability results are compatible with the Adjunct Condition; extraction from the adjunct clauses produced ratings that fell below the mid-point of the scale across all conditions.

Implications for the permeability of adjunct islands:
Our finding that coherence and finiteness have an impact on the acceptability of extraction from adjuncts as well as on the processing of such structures at the point of filler integration suggests that filler-gap integration need not be suspended in adjunct clauses, as has been claimed for other islands (Stowe, 1986; Traxler & Pickering, 1996).

This suggests that some degree of filler-gap integration takes place inside the adjunct islands investigated here (i.e., the extraction is judged to be of low acceptability). See Tunyanian et al. (2017) for similar observations regarding relative clause islands.

How can the permeability of adjunct islands be reconciled with the Adjunct Condition?
- Our stimuli may have forced integration inside the island, due to the absence of another gap; this forced integration was facilitated in the presence of a coherence relation.
- Gap assignment may be supported in the presence of a cue that suggests a tighter semantic relation (coherence) between the adjunct and the matrix clause (e.g. the telicity of the matrix verb) which may also support the overall coherence by finiteness interaction at the wrap-up region (Exp. 2), which suggests that some of the permeability is only visible in the coherent conditions.
